

1. With '===' no type conversion is applied. This means that if the datatypes differ, *false* is always returned. '==' Evaluates the expressions after converting the datatypes, if necessary.
2. A closure is when a function references an instance of a local variable by accessing its outer scope.
3. Higher order functions are functions that can take other functions as parameters and return another function as a result. This can be used for instance to write a template function, through which new functions can be built.
4. The queryselector is method that returns the first element in a document that matches the specified css selector.
